## Perceptron Revisited: Linear Separators

 Binary classification can be viewed as the task of separating classes in feature space:

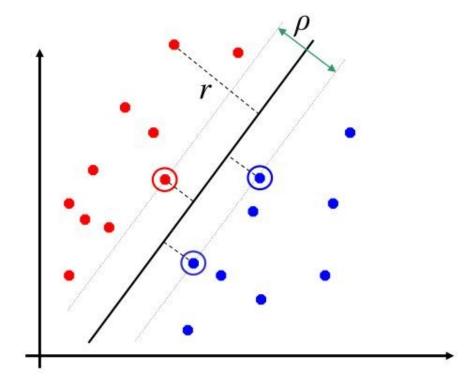

## **Linear Separators**

• Which of the linear separators is optimal?

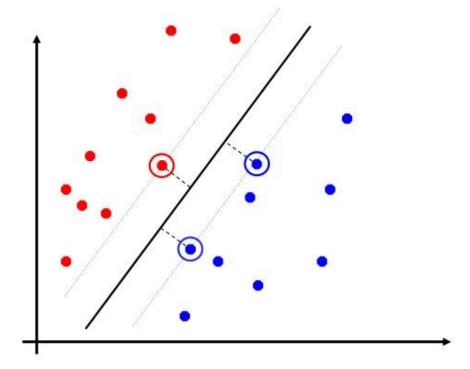

## Classification Margin

- Distance from example  $\mathbf{x}_i$  to the separator is  $r = \frac{\mathbf{w}^T \mathbf{x}_i + b}{\|\mathbf{w}\|}$
- Examples closest to the hyperplane are support vectors.
- *Margin*  $\rho$  of the separator is the distance between support vectors.

## Maximum Margin Classification

- Maximizing the margin is good according to intuition and PAC theory.
- Implies that only support vectors matter; other training examples are ignorable.

## Linear SVM Mathematically

• Let training set  $\{(\mathbf{x}_i, y_i)\}_{i=1..n}$ ,  $\mathbf{x}_i \in \mathbb{R}^d$ ,  $y_i \in \{-1, 1\}$  be separated by a hyperplane with margin  $\rho$ . Then for each training example  $(\mathbf{x}_i, y_i)$ :

$$\mathbf{w}^{\mathbf{T}}\mathbf{x}_{i} + b \le -\rho/2 \quad \text{if } y_{i} = -1 \\ \mathbf{w}^{\mathbf{T}}\mathbf{x}_{i} + b \ge \rho/2 \quad \text{if } y_{i} = 1 \quad \Leftrightarrow \quad y_{i}(\mathbf{w}^{\mathbf{T}}\mathbf{x}_{i} + b) \ge \rho/2$$

- For every support vector  $\mathbf{x}_s$  the above inequality is an equality. After rescaling  $\mathbf{w}$  and b by  $\rho/2$  in the equality, we obtain that distance between each  $\mathbf{x}_s$  and the hyperplane is  $r = \frac{\mathbf{y}_s(\mathbf{w}^T\mathbf{x}_s + b)}{\|\mathbf{w}\|} = \frac{1}{\|\mathbf{w}\|}$
- Then the margin can be expressed through (rescaled) w and b as:

$$\rho = 2r = \frac{2}{\|\mathbf{w}\|}$$

## Linear SVMs Mathematically (cont.)

• Then we can formulate the *quadratic optimization problem*:

Find w and b such that

$$\rho = \frac{2}{\|\mathbf{w}\|}$$
 is maximized

and for all  $(\mathbf{x}_i, y_i)$ , i=1..n:  $y_i(\mathbf{w}^T\mathbf{x}_i + b) \ge 1$ 

Which can be reformulated as:

Find w and b such that

$$\Phi(\mathbf{w}) = ||\mathbf{w}||^2 = \mathbf{w}^T \mathbf{w}$$
 is minimized

and for all  $(\mathbf{x}_i, y_i)$ , i=1..n:  $y_i (\mathbf{w}^T \mathbf{x}_i + b) \ge 1$ 

## Solving the Optimization Problem

Find **w** and b such that  $\Phi(\mathbf{w}) = \mathbf{w}^{\mathrm{T}}\mathbf{w}$  is minimized and for all  $(\mathbf{x}_{i}, y_{i})$ , i=1..n:  $y_{i} (\mathbf{w}^{\mathrm{T}}\mathbf{x}_{i} + b) \ge 1$ 

- Need to optimize a quadratic function subject to linear constraints.
- Quadratic optimization problems are a well-known class of mathematical programming problems for which several (non-trivial) algorithms exist.
- The solution involves constructing a *dual problem* where a *Lagrange* multiplier  $\alpha_i$  is associated with every inequality constraint in the primal (original) problem:

Find  $\alpha_1...\alpha_n$  such that

$$\mathbf{Q}(\mathbf{\alpha}) = \sum \alpha_i - \frac{1}{2} \sum \sum \alpha_i \alpha_i y_i y_j \mathbf{x}_i^T \mathbf{x}_j$$
 is maximized and

- (1)  $\sum \alpha_i y_i = 0$
- (2)  $\alpha_i \ge 0$  for all  $\alpha_i$

## The Optimization Problem Solution

• Given a solution  $\alpha_1...\alpha_n$  to the dual problem, solution to the primal is:

$$\mathbf{w} = \sum \alpha_i y_i \mathbf{x}_i \qquad b = y_k - \sum \alpha_i y_i \mathbf{x}_i^{\mathsf{T}} \mathbf{x}_k \quad \text{for any } \alpha_k > 0$$

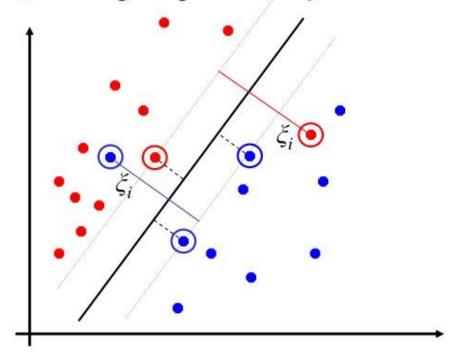

- Each non-zero  $\alpha_i$  indicates that corresponding  $\mathbf{x}_i$  is a support vector.
- Then the classifying function is (note that we don't need w explicitly):

$$f(\mathbf{x}) = \sum \alpha_i y_i \mathbf{x}_i^{\mathsf{T}} \mathbf{x} + b$$

- Notice that it relies on an *inner product* between the test point  $\mathbf{x}$  and the support vectors  $\mathbf{x}_i$  we will return to this later.
- Also keep in mind that solving the optimization problem involved computing the inner products  $\mathbf{x}_i^T \mathbf{x}_i$  between all training points.

## Soft Margin Classification

- What if the training set is not linearly separable?
- Slack variables  $\xi_i$  can be added to allow misclassification of difficult or noisy examples, resulting margin called soft.

## Soft Margin Classification Mathematically

The old formulation:

Find w and b such that  $\Phi(\mathbf{w}) = \mathbf{w}^{\mathrm{T}}\mathbf{w}$  is minimized and for all  $(\mathbf{x}_i, y_i)$ , i=1..n:  $y_i (\mathbf{w}^{\mathrm{T}}\mathbf{x}_i + b) \ge 1$ 

Modified formulation incorporates slack variables:

Find  $\mathbf{w}$  and  $\mathbf{b}$  such that  $\mathbf{\Phi}(\mathbf{w}) = \mathbf{w}^{\mathrm{T}}\mathbf{w} + C\Sigma \xi_{i} \text{ is minimized}$  and for all  $(\mathbf{x}_{i}, y_{i}), i=1..n: \quad y_{i} (\mathbf{w}^{\mathrm{T}}\mathbf{x}_{i} + b) \geq 1 - \xi_{i}, \quad \xi_{i} \geq 0$ 

• Parameter C can be viewed as a way to control overfitting: it "trades off" the relative importance of maximizing the margin and fitting the training data.

## Soft Margin Classification - Solution

• Dual problem is identical to separable case (would *not* be identical if the 2-norm penalty for slack variables  $C\Sigma \xi_i^2$  was used in primal objective, we would need additional Lagrange multipliers for slack variables):

Find 
$$\alpha_1 ... \alpha_N$$
 such that

$$\mathbf{Q}(\mathbf{\alpha}) = \sum \alpha_i - \frac{1}{2} \sum \sum \alpha_i \alpha_j y_i y_j \mathbf{x}_i^T \mathbf{x}_j$$
 is maximized and

- (1)  $\sum \alpha_i y_i = 0$
- (2)  $0 \le \alpha_i \le C$  for all  $\alpha_i$
- Again,  $\mathbf{x}_i$  with non-zero  $\alpha_i$  will be support vectors.
- Solution to the dual problem is:

$$\mathbf{w} = \sum \alpha_i y_i \mathbf{x}_i$$

$$b = y_k (1 - \xi_k) - \sum \alpha_i y_i \mathbf{x}_i^{\mathsf{T}} \mathbf{x}_k \quad \text{for any } k \text{ s.t. } \alpha_k > 0$$

Again, we don't need to compute **w** explicitly for classification:

$$f(\mathbf{x}) = \sum \alpha_i y_i \mathbf{x}_i^{\mathsf{T}} \mathbf{x} + b$$

# Theoretical Justification for Maximum Margins

Vapnik has proved the following:

The class of optimal linear separators has VC dimension h bounded from

above as

 $h \le \min\left\{ \left\lceil \frac{D^2}{\rho^2} \right\rceil, m_0 \right\} + 1$ 

where  $\rho$  is the margin, D is the diameter of the smallest sphere that can enclose all of the training examples, and  $m_0$  is the dimensionality.

- Intuitively, this implies that regardless of dimensionality  $m_0$  we can minimize the VC dimension by maximizing the margin  $\rho$ .
- Thus, complexity of the classifier is kept small regardless of dimensionality.

### Linear SVMs: Overview

- The classifier is a *separating hyperplane*.
- Most "important" training points are support vectors; they define the hyperplane.
- Quadratic optimization algorithms can identify which training points  $\mathbf{x}_i$  are support vectors with non-zero Lagrangian multipliers  $\alpha_i$ .
- Both in the dual formulation of the problem and in the solution training points appear only inside inner products:

Find  $\alpha_1 ... \alpha_N$  such that

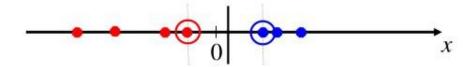

$$\mathbf{Q}(\boldsymbol{\alpha}) = \sum \alpha_i - \frac{1}{2} \sum \sum \alpha_i \alpha_j y_i y_j \mathbf{x}_i^T \mathbf{x}_j$$
 is maximized and

- (1)  $\sum \alpha_i y_i = 0$
- (2)  $0 \le \alpha_i \le C$  for all  $\alpha_i$

$$f(\mathbf{x}) = \sum \alpha_i y_i \mathbf{x}_i^{\mathsf{T}} \mathbf{x} + b$$

#### Non-linear SVMs

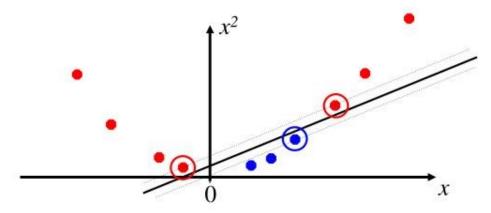

Datasets that are linearly separable with some noise work out great:

But what are we going to do if the dataset is just too hard?

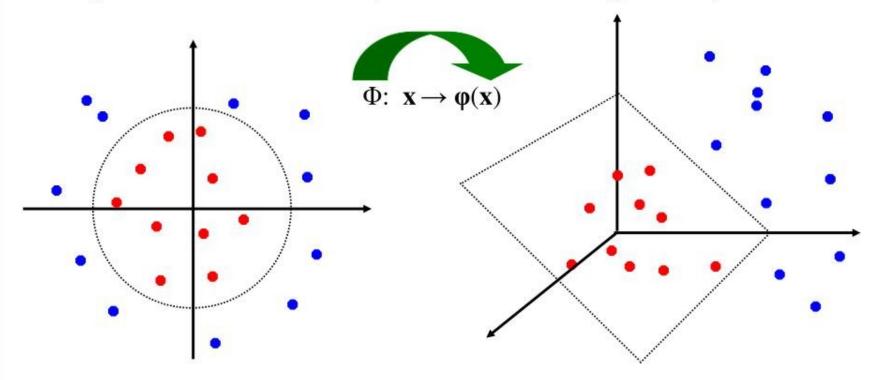

How about... mapping data to a higher-dimensional space:

## Non-linear SVMs: Feature spaces

 General idea: the original feature space can always be mapped to some higher-dimensional feature space where the training set is separable:

#### The "Kernel Trick"

- The linear classifier relies on inner product between vectors  $K(\mathbf{x}_i, \mathbf{x}_j) = \mathbf{x}_i^T \mathbf{x}_j$
- If every datapoint is mapped into high-dimensional space via some transformation Φ: x→ φ(x), the inner product becomes:

$$K(\mathbf{x}_i, \mathbf{x}_j) = \mathbf{\varphi}(\mathbf{x}_i)^{\mathrm{T}} \mathbf{\varphi}(\mathbf{x}_j)$$

- A *kernel function* is a function that is equivalent to an inner product in some feature space.
- Example:

2-dimensional vectors  $\mathbf{x} = [x_1 \ x_2]$ ; let  $K(\mathbf{x}_i, \mathbf{x}_j) = (1 + \mathbf{x}_i^T \mathbf{x}_j)^2$ ,

Need to show that  $K(\mathbf{x}_i, \mathbf{x}_j) = \varphi(\mathbf{x}_i)^T \varphi(\mathbf{x}_j)$ :

$$K(\mathbf{x}_{i}, \mathbf{x}_{j}) = (1 + \mathbf{x}_{i}^{\mathsf{T}} \mathbf{x}_{j})^{2} = 1 + x_{i1}^{2} x_{j1}^{2} + 2 x_{i1} x_{j1} x_{i2} x_{j2} + x_{i2}^{2} x_{j2}^{2} + 2 x_{i1} x_{j1} + 2 x_{i2} x_{j2} = 1 + x_{i1}^{2} x_{j1}^{2} + 2 x_{i1}^{2} x_{j1}^{2} + 2 x_{i1}^{2} x_{j2}^{2} + 2 x_{i1}^{2} x_{j2}^{2} + 2 x_{i1}^{2} x_{j2}^{2} = 1 + x_{i1}^{2} x_{j1}^{2} + 2 x_{i1}^{2} x_{j1}^{2} + 2 x_{i2}^{2} x_{j2}^{2} + 2 x_{i1}^{2} x_{j2}^{2} + 2 x_{i1}^{2} x_{j2}^{2} = 1 + x_{i1}^{2} x_{j1}^{2} + 2 x_{i1}^{2} x_{j2}^{2} + 2 x_{i1}^{2} x_{j1}^{2} + 2 x_{i2}^{2} x_{j2}^{2} = 1 + x_{i1}^{2} x_{j1}^{2} + 2 x_{i1}^{2} x_{j1}^{2} + 2 x_{i1}^{2} x_{j2}^{2} + 2 x_{i1}^{2} x_{j1}^{2} + 2 x_{i2}^{2} x_{j2}^{2} = 1 + x_{i1}^{2} x_{j1}^{2} + 2 x_{i1}^{2} x_{j2}^{2} + 2 x_{i1}^{2} x_{j1}^{2} + 2 x_{i2}^{2} x_{j2}^{2} = 1 + x_{i1}^{2} x_{j1}^{2} + 2 x_{i1}^{2} x_{j1}^{2} + 2 x_{i1}^{2} x_{j2}^{2} + 2 x_{i1}^{2} x_{j1}^{2} + 2 x_{i2}^{2} x_{j2}^{2} = 1 + x_{i1}^{2} x_{j1}^{2} + 2 x_{i1}^{2} x_{j1}^{2} + 2 x_{i2}^{2} x_{j2}^{2} + 2 x_{i1}^{2} x_{j2}^{2} + 2 x$$

• Thus, a kernel function *implicitly* maps data to a high-dimensional space (without the need to compute each  $\varphi(\mathbf{x})$  explicitly).

### What Functions are Kernels?

- For some functions  $K(\mathbf{x}_i, \mathbf{x}_j)$  checking that  $K(\mathbf{x}_i, \mathbf{x}_j) = \varphi(\mathbf{x}_i)^T \varphi(\mathbf{x}_j)$  can be cumbersome.
- Mercer's theorem:

#### Every semi-positive definite symmetric function is a kernel

 Semi-positive definite symmetric functions correspond to a semi-positive definite symmetric Gram matrix:

	$K(\mathbf{x}_1,\mathbf{x}_1)$	$K(\mathbf{x}_1,\mathbf{x}_2)$	$K(\mathbf{x}_1,\mathbf{x}_3)$	***	$K(\mathbf{x}_1,\mathbf{x}_n)$
	$K(\mathbf{x}_2,\mathbf{x}_1)$	$K(\mathbf{x}_2,\mathbf{x}_2)$	$K(\mathbf{x}_2,\mathbf{x}_3)$		$K(\mathbf{x}_2,\mathbf{x}_n)$
K=					1000
	$K(\mathbf{x}_n, \mathbf{x}_1)$	$K(\mathbf{x}_n, \mathbf{x}_2)$	$K(\mathbf{x}_n,\mathbf{x}_3)$		$K(\mathbf{x}_n, \mathbf{x}_n)$

## **Examples of Kernel Functions**

- Linear:  $K(\mathbf{x}_i, \mathbf{x}_i) = \mathbf{x}_i^T \mathbf{x}_i$ 
  - Mapping  $\Phi$ :  $\mathbf{x} \to \phi(\mathbf{x})$ , where  $\phi(\mathbf{x})$  is  $\mathbf{x}$  itself
- Polynomial of power  $p: K(\mathbf{x}_i, \mathbf{x}_j) = (1 + \mathbf{x}_i^T \mathbf{x}_j)^p$  Mapping  $\Phi: \mathbf{x} \to \varphi(\mathbf{x})$ , where  $\varphi(\mathbf{x})$  has  $\binom{d+p}{p}$  dimensions
- $\frac{\left\|\mathbf{x}_{i}-\mathbf{x}_{j}\right\|^{2}}{2\sigma^{2}}$ Gaussian (radial-basis function):  $K(\mathbf{x}_i, \mathbf{x}_i) = e$ 
  - Mapping  $\Phi$ :  $\mathbf{x} \to \mathbf{\phi}(\mathbf{x})$ , where  $\mathbf{\phi}(\mathbf{x})$  is *infinite-dimensional*: every point is mapped to a function (a Gaussian); combination of functions for support vectors is the separator.
- Higher-dimensional space still has *intrinsic* dimensionality d (the mapping is not *onto*), but linear separators in it correspond to *non-linear* separators in original space.

# Non-linear SVMs Mathematically

• Dual problem formulation:

Find  $\alpha_1 ... \alpha_n$  such that

$$\mathbf{Q}(\mathbf{\alpha}) = \sum \alpha_i - \frac{1}{2} \sum \sum \alpha_i \alpha_j y_i y_j K(\mathbf{x}_i, \mathbf{x}_j)$$
 is maximized and

- (1)  $\sum \alpha_i y_i = 0$
- (2)  $\alpha_i \ge 0$  for all  $\alpha_i$
- The solution is:

$$f(\mathbf{x}) = \sum \alpha_i y_i K(\mathbf{x}_i, \mathbf{x}_j) + b$$

• Optimization techniques for finding  $\alpha_i$ 's remain the same!

# **SVM** applications

- SVMs were originally proposed by Boser, Guyon and Vapnik in 1992 and gained increasing popularity in late 1990s.
- SVMs are currently among the best performers for a number of classification tasks ranging from text to genomic data.
- SVMs can be applied to complex data types beyond feature vectors (e.g. graphs, sequences, relational data) by designing kernel functions for such data.
- SVM techniques have been extended to a number of tasks such as regression [Vapnik *et al.* '97], principal component analysis [Schölkopf *et al.* '99], etc.
- Most popular optimization algorithms for SVMs use *decomposition* to hill-climb over a subset of  $\alpha_i$ 's at a time, e.g. SMO [Platt '99] and [Joachims '99]
- Tuning SVMs remains a black art: selecting a specific kernel and parameters is usually done in a try-and-see manner.
